RE: DRAFT Avalanche Hazard Mapping and Recommendations The Village of Taos Ski Valley, New Mexico

Dear Mr. Nicholson:

This updated Draft Report and accompanying Preliminary Maps have been revised based on additional information, including site observations and comments from local avalanche professionals. The mapping builds on previous work and incorporates new data, methods and research to improve the quality of maps compared to the village's existing Avalanche Hazard Maps prepared by Arthur I. Mears, P.E., Inc. in 2001.

We recommend that you, your staff and all other stakeholders review this report and maps. We welcome any new information or feedback and will take it into account prior to finalizing the report and maps.

We have enjoyed working on this project. We hope that this provides the information that you need at this time. If you have any questions, please contact me.

Sincerely, Wilbur Engineering, Inc.

21.1

Chris Wilbur, P.E.

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

1. Background

This report describes a site-specific avalanche hazard mapping study for the Village of Taos Ski Valley. Figure 1 shows a site location map.

Figure 1 – Site Location

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

2. Objectives

This report has the following **objectives**:

- 1. Describe the regional snow and avalanche climate.
- 2. Determine the runout limits of snow avalanches with average return periods of 100-years and 300-years or annual exceedance probabilities of 1.0 percent and 0.3-percent;
- 3. Describe methods used to develop the Avalanche Hazard Map.
- 4. Delineate Avalanche Zones as defined in this report.
 - a. High Hazard (Red) frequent or high energy¹ avalanches zones.
 - b. Moderate Hazard (Blue) low frequency and low-medium energy².
 - c. Low Hazard (Yellow) areas subject to low probability/low energy dense flowing avalanches or medium-frequency/low energy powder avalanche impacts³.
- 5. Describe avalanche risks in relation to the land use, along with uncertainties, and recommendations for mitigating avalanches hazards within and near the defined hazard zones.
- 6. Provide information and guidance on the existing avalanche ordinance and potential future revisions.

3. Limitations

This report also has the following **limitations**, which must be understood by all those relying on the results, conclusions, and recommendations:

- 1. Avalanches larger than the mapped avalanche runouts are possible, even though the probabilities are low.
- 2. This study is site and time specific; it should not be applied to adjacent lands nor should it be used without updating in the future when additional data and improved methods become available.
- 3. The avalanche hazard boundaries are based on current topography, vegetation and climatic conditions. Changes in any of these conditions could increase or decrease the avalanche hazard.

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

¹ The *Red Zone* is an area where avalanches have a return period of 30 years or less or produce impact pressures of 600 lbs/ft² or greater on a flat surface normal to flow.

² The *Blue Zone* is defined as an area where avalanches have a return period ranging from 30 to 100 years (3% to 1.0% annual probability) and where avalanches produce impact pressures of less than 600 lbs/ft² on a flat surface normal to flow.

³ The *Yellow Zone* is defined as an area where avalanches have estimated average return periods between 100 and 300-years and powder pressures are less than 60 psf.

- 4. The effects of ongoing fire mitigation efforts on avalanche hazards are difficult to quantify and we requested, but not received fire mitigation prescriptions or maps, except for the Northside area.
- 5. Site specific mitigation of structures including buildings, roads, and parking areas are beyond the scope of this study.
- 6. This report does not address avalanche risks to persons traveling, working in or recreating in avalanche terrain. This type of avalanche risk must be addressed with an ongoing operational avalanche plan that includes weather and snowpack monitoring, forecasting and temporary mitigation measures, such as terrain and road closures.

4. Methods

The avalanche hazard mapping and recommendations presented in this report are based on:

- 1. Site observations made by Chris Wilbur, P.E. on September 15 and 16, 2022 and January 13, March 19, and April 11, 2023.
- 2. Interviews and email correspondence with knowledgeable persons, including Rachel Moscarella, Kevin Beardsley, Alex Mithoefer (TSVI Snow Safety) and Andy Bond (Taos Avalanche Center).
- 3. Analysis of aerial photos of various dates and sources (Village of Taos Ski Valley, USGS, NAIP, Google Earth, Bing);
- 4. Review of historic weather data, include data from Taos Ski Valley, Inc., and the Powderhorn Snotel site.
- 5. Terrain analysis using 2015 LiDAR data from the USGS National Map.
- 6. Application of statistical avalanche runout models.
- 7. Avalanche dynamic modeling with the Swiss program, RAMMS, Version 1.80 utilizing a digital elevation model (DEM) developed from the LiDAR data.
- 8. Avalanche dynamic modeling of the suspension component with the Swiss program, RAMMS:Extended, version 2.7.90.
- 9. A review of published documents on the effects of forests on avalanche processes.
- 10. Our local and regional knowledge of terrain, climate and avalanche hazards.

5. Snow Climate

The Taos Ski Valley and Sangre de Cristo mountains are characterized by a continental snow climate typical of high elevations in northern New Mexico. Average annual precipitation at the Village of Taos Ski Valley is 20.5 inches and average snowfall is about 146 inches. Average January low and high temperatures are 4°F and 21°F,

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

respectively. Precipitation generally increases and temperatures decrease at higher elevations. This relatively dry, sunny snow climate commonly has a shallow weak earlyseason snowpack that can persist throughout the winter and spring. The weak lower snowpack can become overloaded by snow slabs that form during large storms and wind events, resulting in instability and widespread natural and triggered avalanche activity. Wet avalanches are common during springtime warm weather, including after the ski area is closed. Weather and climate data are presented in Appendix A.

6. Avalanche Terrain

Figure 2 shows a slope-angle map derived from the USGS 2015 LiDAR data. Figure 3 shows an aspect map. The orange and red colors on the slope map indicate potential avalanche starting zones. Most avalanche starting zones⁴ have slope angles of between 30 and 45 degrees. Northerly aspects that will accumulate a deeper and colder snowpack than other aspects. Southerly aspects will hold less snow causing surface roughness to reduce the probability and size of avalanches. However, prolonged storms can result in large avalanches on south-facing terrain. Prevailing winds will transport snow onto NE through SE aspects. Less common easterly winds can load starting zones above timberline on the east side of the Lake Fork.

Avalanche tracks⁵ at the site range from incised gullies to sub-planar slopes. Some of the lower tracks turn abruptly at the main valley. The avalanche runout zones⁶ include relatively steep channels, valley bottoms and debris fans. Many of the runout zones at the site are relatively steep (>10-degrees) because the size of avalanche releases is inhibited by forested starting zones. Exceptions occur above timberline and in disturbed areas such as the Mineslide path.

Figure 4 shows evidence of an undocumented large avalanche at the Northside that destroyed forests at the site in the early 1960s. This avalanche might have occurred during a major avalanche cycle in the southern Rocky Mountains that occurred in late January 1962. An avalanche cycle in the mid-1990s also extended into forested terrain at the southern end of the map area.

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

⁴ The *Starting Zone* of an avalanche is the area where snow releases, accelerates and increases in mass.

⁵ The *Track* of an avalanche is the area where maximum velocity and mass are attained.

⁶ The *Runout Zone* is the area where avalanches decelerate, deposit and come to a stop.

Figure 2 – Slope Map

7. Statistical Avalanche Runout Models

We applied statistical avalanche runout models from eight avalanche climates to estimate potential ranges of extreme (100 to 300-year average return periods) avalanche runout distances for selected paths (Ref. 4). These models use a centerline profile of the avalanche path and incorporate the "beta-point" which is the location where the slope angle decreases to 10-degrees. No regional or site-specific models exist for the Taos Ski Valley area, so the statistical models are intended only as a supplemental method to bracket likely ranges of extreme runouts. Figure 5 shows centerline profiles with mapped and modeled runouts of selected avalanche paths.

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

Figure 5 – Avalanche Profiles and Locations

8. Forest Conditions

The role of forests in preventing snow avalanches in steep terrain has long been recognized in Europe where destructive avalanches resulted from tree removal for buildings and firewood. More recently, fires and logging operations in the U.S. and Canada have led to a better understanding of the role of forests in avalanche prevention and mitigation. The following factors have been found to reduce avalanche release frequencies, sizes and runout distances:

1. Tree canopy coverage, especially conifers, influences snow accumulation depth and variability; Tree canopy disrupts snowpack structure and reduces crusts continuous weak layers; Tree canopy changes energy balance caused by incoming and outgoing radiation resulting in a generally stronger snowpack;

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

- 2. Tree trunks anchor the snowpack in *starting zones* by mechanical resistance to creep, glide and slab failure. This effect is dependent on relatively high density of medium-large trees per acre.
- 3. Forests in the *track* and *runout zones* have a relatively small effect on runout distance compared to the above factors. The effects of friction and energy dissipation due to forest impacts in avalanche tracks and runout zones generally decrease with increasing avalanche mass.

The combination of factors listed above cause healthy conifer forests to be more effective than deciduous or mixed forests, or snags at preventing avalanche release. A decrease in forest density and canopy coverage can result from several causes, including insect mortality, forest fire, logging and thinning, and blowdown.

The forest fire history of the upper Rio Hondo watershed is described in Ref. 2, including a map of a high-severity fire that impacted much of the site in 1842 during a severe drought. The 1842 fire burned bristlecone pines near timberline. The report includes several historic (~1903) photos indicating severe burn areas at the Northside and the east side of the Lake Fork. Figure 6 shows a historic photo of Twining and the Mineslide path.

Figure 6 – Historic Photo of Mineslide and Northside Area (Source: USFS interpretive sign, © private photo)

A major forest blowdown event occurred in mid-December 2021, destroying and damaging numerous buildings in Taos county, resulting a county-wide state of emergency declaration. Thousands of trees were blown down above Twining Road near

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

the Bavarian Restaurant, the Phoenix, Lift 4 and on both sides of the valley up the William's Lake trail. Figure 7 shows a map of the blowdown area near the site. Figure 8 shows a photo of the blowdown area taken in August 2022.

Figure 7 – Map of December 2021 Severe Blowdown Area (Source DEI Report; Avalanche Paths from Mears 2000 Maps)

A Forest Management Plan for the Northside at Taos Ski Valley was prepared in 2020 by Dolecek Enterprises Inc. (DEI), Forest Management Specialists (Ref. 3). The plan describes declining forest heath over the last 30 years at the Northside at Taos Ski Valley and throughout the Southwest. The Northside at Taos Ski Valley is classified as a very high fire risk, with potential for severe fire intensity on the New Mexico Fire Risk Portal. The DEI Report includes a prescription for the 1962 avalanche path starting zone based on the high basal area (238) and its location above the Bull of the Woods spring.

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

Figure 8 – Photo of December 2021 Blowdown Area (Chris Wilbur Photo, August 2022)

Fire mitigation withing the ski resort's permit area have been ongoing. Figure 9 shows areas of mitigation that consist mainly of removal of dead standing and downed trees.

INSERT FIGURE (pending)

Figure 9 – Taos Ski Valley, Inc. Fire Mitigation Map

We observed areas of thinning during our field observations, including lop and pile in potential avalanche starting zones. Figure 10 shows a forest canopy height from the Frontside derived from 2015 LiDAR data. Figure 11 shows a canopy height map from the Northside. These figures are based on pre-fire mitigation conditions. Additional forest and vegetation photos and their locations are shown in Appendix B.

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

9. Avalanche Dynamics Modeling

We used the Swiss avalanche dynamics program RAMMS to evaluate flow directions, flow thicknesses, velocities and runouts for the various potential avalanche starting zones and paths. We applied a range of parameters to evaluate sensitivity and the influence of release areas, friction and flow regimes. Friction parameters were based on calibration guidelines provided in the RAMMS Version 1.7.2 User Manual and based on

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

elevation, avalanche size, terrain shape and return period. High elevation friction parameters (greater than 1500 meters in Switzerland) were assumed due to relatively dry cold snowpack conditions. We included cohesion and forest friction to improve calibration for small forested paths. The model calibration was based on our experience with other avalanches, including documented historic avalanches at Taos Ski Valley.

Figure 12 shows representative model results for the dense flowing core of the 100-year avalanche. Figure 13 shows representative model results for the suspension component of a 100-year avalanche. Model input assumptions and additional results are presented in Appendix C.

Figure 12 – Representative RAMMS Model Results

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

Figure 13 – Bavarian Path Powder Pressure from RAMMS:Extended Model

10. Findings

Based on the methods described in this report, we developed Avalanche Hazard Maps for the entire village limits (Maps 1 through 5). The avalanche hazard zone definitions are consistent with those in the report by Arthur I. Mears, P.E., Inc. *Snow Avalanche Mapping and Zoning with Land Use Recommendations,* prepared for the Village of Taos Ski Valley in 2001, except that the Yellow (Low) Avalanche Hazard Zone has been added. The Red and Blue Zone definitions are unchanged. The available topography, aerial imagery and avalanche dynamics models have significantly improved since the 2001 Avalanche Hazard Maps.

Each of the methods used to develop the avalanche hazard maps was weighted based on our relative confidence in the method. Weighting was similarly high for field vegetation observations, aerial image analysis, terrain analysis and dynamics modeling. Statistical methods were underweighted primarily due to forests that inhibit avalanche releases and the relatively low snow depths on southerly aspects.

Fire mitigation measures in many areas steeper than 30 degrees have reduced forest density necessary to prevent avalanche releases. As a result, the frequency and size of avalanches in these areas is likely to increase compared to historic conditions. Over time as the forest grow, the hazards may decrease and approach historic levels. The Avalanche hazard maps reflect current forest conditions, including thinning that has occurred to date. Prevention of high-intensity fires in the starting zones is critical

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

because complete loss of forest in the starting zones would increase the hazard boundaries well beyond the limits for current conditions.

Snow compaction and layer disruptions from ski area operations will significantly reduce the frequencies and sizes of avalanches with return periods up to about 30-years. Between return periods of 30- and 100-years declining reductions in hazard will occur. Compaction operations' effects on 300-year avalanches will be negligible.

11. Uncertainties

There are several sources of uncertainty that could affect current and future avalanche hazards. We describe these briefly below.

Avalanche Processes

Avalanche mapping science has advanced considerably in recent years, but it is still an immature science. The latest avalanche dynamics models under development consider snow temperature and avalanche flow regimes in a thermodynamic context, which has relevance in a warming climate. However, large uncertainties exist about the input parameters and applicability to various snow-avalanche climates. This high elevation-low latitude, windy snow climate differs from those in Europe where much of the science and models were developed.

Data and Records

The historic records are very limited, incomplete and private records are not readily available.

Climate

Avalanches of concern for land use planning are affected by forest conditions (especially in the starting zones), snow temperatures, precipitation intensities and snowpack structure. These factors are likely to change over time in a warming climate. Combined, some climate factors offset others, but any of them could result in higher frequencies and magnitudes of unusually long-running avalanches. There are large uncertainties, but it is likely that avalanche frequency-magnitudes will change over time. It is our opinion that avalanche hazards in this snow climate may increase in the next decades due to increases in storm intensities, precipitation and winds. Warming temperatures may have the effect of allowing thicker snow slabs to accumulate on low to modest angle starting zones (30-35 degrees) before large releases. Such avalanches will have long runouts for both wet and dry releases. Rain-on-snow events can trigger

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

avalanches and these events are expected to become more frequent in a warming climate.

Forest Conditions

The high-elevation, subalpine forests play a crucial role in avalanche mitigation on all aspects. Current forest conditions on many steep northerly slopes (>30-degrees) prevent the release of large avalanches. Loss of forests caused by fire, blowdown, clearing or any other cause will adversely affect the avalanche hazards, increasing the frequency and magnitude of avalanches. Conversely, active management of tree spacings, canopy densities, ages, species and ground cover could stabilize and eventually reduce avalanche hazards levels. While efforts to improve forest health are planned and underway, it is impossible for us to predict future forest conditions.

Table 1 summarizes literature related to forest density and avalanche release. The data in Table 1 are based on a very short period of observation and do not necessary apply to long-return period avalanches.

 Table 1 - Protection Forest Guidelines

12. Avalanche Risk

The following information is intended to provide context for the recommendations provided in the following section of this report, especially as they relate to hazard zoning, land use, occupied buildings, and exposure to avalanche hazards.

Avalanche risk is defined as the probability of injury, death or losses caused by an avalanche. Risk can be expressed as the product of probability, magnitude, exposure and vulnerability. Each component contributes to the risk.

$$\mathsf{R} = \mathsf{f}(\mathsf{P}, \mathsf{M}, \mathsf{E}, \mathsf{V})$$

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

Risk, R, can be reduced to an acceptable level by reducing any one or more of the risk factors. Zoning maps reflect the probability-magnitude elements. Land use decisions (dwelling locations and unit-density) and mitigation designs (structural, architectural, civil) affect the exposure and vulnerability components. Exposure (E) includes both time and numbers of people or value of resources for a given location. Exposure can be reduced by structural and architectural designs that place high occupancy uses in protected areas. This is particularly important for outdoor uses such as hot tubs, entries and outdoor living spaces. Vulnerability (V) is the resistance to loss. Persons inside of buildings designed for avalanche impact have a high level of protection, but outside of buildings, vulnerability is high. Vulnerability for persons outside of buildings is best managed by designs and user awareness that minimize the time of exposure.

Each component of risk involves uncertainties. The probability-magnitude uncertainties for avalanche hazards are generally larger than the uncertainties for vulnerabilities due to the short historic record and limitations of avalanche mapping science.

13. Recommendations

Land Use

- 1. No occupied or valuable structures should be constructed in the Red Avalanche Hazard Zones.
- 2. Occupied and valuable structures should be located outside of the Blue and Yellow Zones, wherever practical.
- 3. No critical structures should be constructed in the Blue or Yellow Zones. Critical structures include emergency response facilities (police, fire, ambulance, clinics), hospitals and schools.
- 4. No high-occupancy structures (hotels, apartments, auditoriums, etc.) should be constructed in the Red or Blue Zones.
- 5. If low-occupancy, residential or commercial structures are constructed in the Blue Avalanche Hazard Zones, they should be located as low as practical in the Blue Zone and designed to withstand avalanche impact and static loads. Avalanche loads cannot be determined until the location, geometry and orientation of the structures are known.
- 6. Based on uncertainties, occupied structures in the Yellow (Low) Avalanche Hazard Zone should be designed to withstand avalanche impact and static loads. In larger avalanche paths (more than 1000 vertical foot fall), stagnation pressures from the suspension component (powder blast) can act to heights of 50-feet or more. Avalanche loads cannot be determined until the location, geometry and orientation of the structures are known.
- 7. Site and architectural designs should address avalanche hazards in the Blue and Yellow Zones. Building entries and outdoor living spaces, especially hot tubs and heated outdoor spaces, should be placed in protected areas away from the

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

avalanche-facing side of the building. In cases where this is not practical, evacuation plans for exposed areas should be made and implemented. Windows and doors on the uphill side should be avoided or designed for impact.

- 8. All utilities in avalanche zones should be buried. Gas lines, utility meters and fire hydrants in avalanche zones should be protected to prevent damage.
- 9. It is possible to achieve a high level of avalanche protection for occupants inside specially designed, reinforced buildings, but persons and pets outside will not be protected. Therefore, it is prudent for occupants and guests of residential buildings in and near avalanche hazard zones to become educated and keep current on local avalanche conditions, including the local and regional avalanche danger forecasts. However, reliance upon forecasts and avoiding avalanche zones during elevated avalanche danger conditions can reduce, but not eliminate avalanche risk, especially to persons outside of buildings.

Avalanche Ordinance

The following is from Ordinance 17-030:

SECTION 7. GENERAL PROVISIONS.

Part 6. Avalanche Design Requirements

Prior to the Village issuing a building permit for the construction of a new, freestanding building to be occupied by one or more persons, the applicant must provide the following to the Village for review by the Planning Officer:

1. A written report analyzing the potential avalanche hazards and the potential physical forces, if any, created thereby upon the proposed improvement or structure, and;

2. A structural analysis of the proposed building or structure prepared and sealed by a New Mexico licensed engineer reflecting an engineering analysis and design which states that the design of the building or structure can withstand the potential force from an avalanche as set forth in the avalanche report referred above. This analysis shall be required only if the referenced report indicates that an avalanche hazard exists.

3. The issuance of a building permit by the Village shall not be construed to mean that the Village agrees that the proposed building will withstand an avalanche.

The ordinance does not incorporate the 2001 Avalanche Hazard Maps or distinguish between different (Red or Blue) hazard zones. In the U.S., local jurisdictions determine restrictions and requirements for development in avalanche zones. The ranges of restrictions vary from none or few to severe. These are policy decisions that have

DRAFT Avalanche Hazard Assessment Village of Taos Ski Valley Taos Ski Valley, New Mexico

significant impacts on public and private properties. We offer some general guidelines and recommendations:

- 1. The recommendations in the previous section should be incorporated, including distinguishing between hazard zones and allowable land uses, particularly for the Blow and Red Zones.
- 2. The issue of non-conforming structures (e.g. unreinforced buildings in Blue Zones) should be addressed by informing owners and occupants and addressing future additions, improvements or avalanche defenses prior to issuing building permits.
- 3. The ordinance should allow for review and adjustment of avalanche zones based on analyses by a qualified avalanche professional.
- 4. We recommend incorporating avalanche hazard maps into the ordinance with procedures for amendments to the avalanche hazard maps.
- 5. We recommend requiring that new construction does not adversely impact avalanche hazards on adjoining and downhill properties, including public roads and utilities.
- 6. We recommend developing a list of criteria for reviewing developments in avalanche zones.
- 7. We recommend that public officials review avalanche ordinances from other jurisdictions, including Vail Colorado, Pitkin County Colorado, Ketchum, Idaho and Blaine County, Idaho.
- 8. We recommend that thinning be limited on slopes steeper than 30 degrees to the minimum conifer tree densities for trees 6" diameter and larger per Figure 13 to the maximum extent practical. Deciduous and dead/snag tree densities should be double those shown in Figure 13 for avalanche protection. Tree spacing should be relatively even and staggered to avoid fall-line clearings longer than about 50 to 100-feet of slope distance.

Appendix C RAMMS Parameters & Results for Design Magnitude Avalanche

*** Important Note: ***

Interpretation of avalanche dynamics model results requires an understanding of the model assumptions, simplifications and limitations of the underlying equations of motion. The models do not accurately show wet avalanche runouts, flow heights or impact pressures, or the variations in avalanche properties with depth, including density and velocity.
